}
```

Fit linear regression without imputing income

As lots of the incomes are zero, it makes sense to impute these, as employment status is a categorical variable anyway which accounts for those with no income. First we can get a baseline without imputing income.

```
mod <- lm(total_claim_amount ~ vehicle_class + income +
          employment_status*monthly_premium_auto +
          location_code*monthly_premium_auto, data = train_df)
```

```
y_hat <- predict(mod, newdata = test_df)
```

```
summary(mod)
```

```

Default GAM does worse during cross-validation! Not too surprising when you see the plots though as they look very linear. Although I could also be doing something wrong...

Quantile regression

Since we are aiming to minimize the mean absolute error. Perhaps fitting a linear model using median regression will likely perform better. This is optimal for minimizing mean absolute error, whereas the mean is optimal for the squared error loss function.

```

## [1] "MAE of: 79.4"
```

This performs a lot better. We should be able to simplify things further based on the zero coefficients above.

Note that here we use the pairwise bootstrap estimate of the standard errors. This is more robust to heteroscedasticity than the standard method (e.g. see this paper). We can see that we have heteroscedasticity here:

```
plot(test_df$monthly_premium_auto, (y_hat-test_df$total_claim_amount),
      xlab = "monthly_premium_auto", ylab = "rediduals")
```

We will slim things down and simplify the model to make a final model:

Final Model

Simplify using the following:

- Simplify `employment_status` into a boolean `is_employed`, as being unemployed was the only significant factor level.
- Drop income and vehicle class

```
train_df_simple <- train_df %>%
  mutate(is_unemployed = employment_status == "Unemployed") %>%
  select(-employment_status, -income, -vehicle_class)

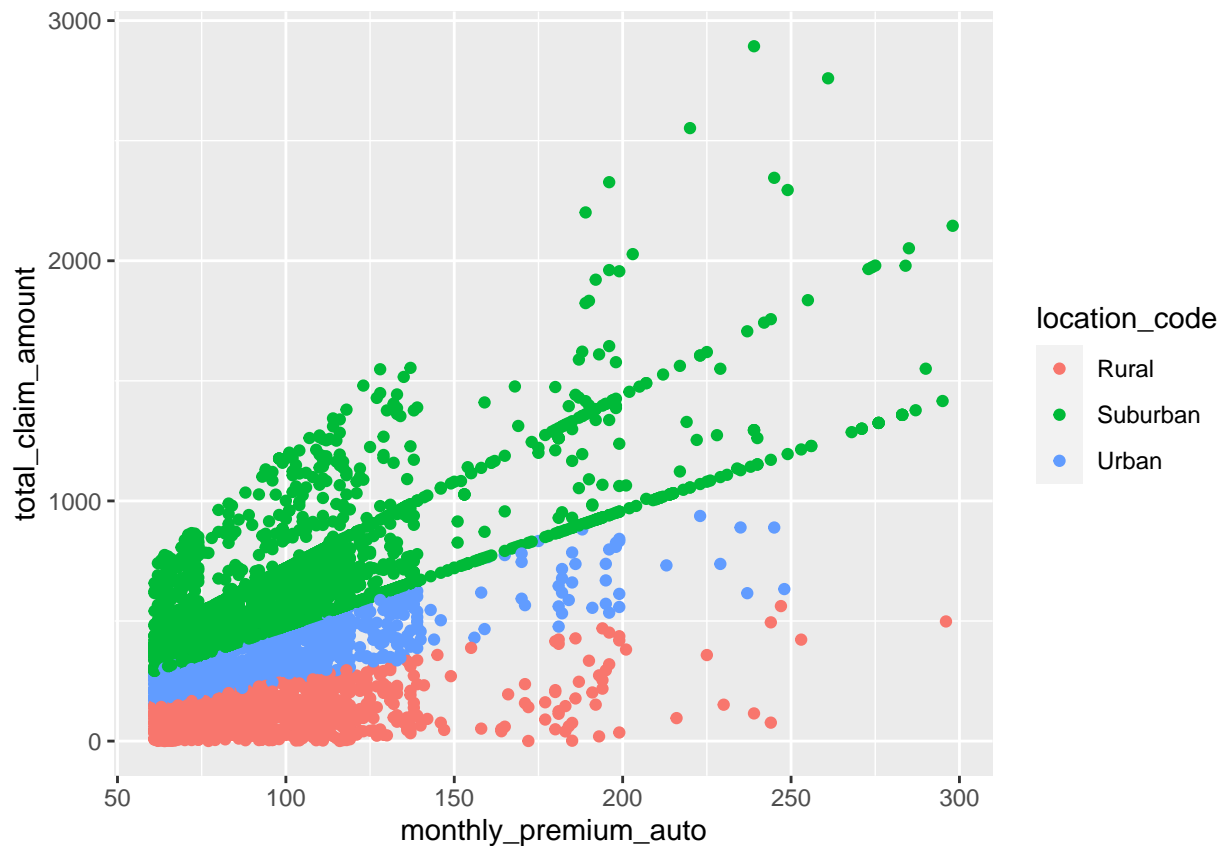

test_df_simple <- test_df %>%
  mutate(is_unemployed = employment_status == "Unemployed") %>%
  select(-employment_status, -income, -vehicle_class)

head(train_df_simple)
```

```
##      location_code monthly_premium_auto total_claim_amount is_unemployed
## 1352          Urban                67          172.5185         FALSE
## 7760        Suburban               129          928.8000          TRUE
## 4393        Suburban               112         1169.4098         FALSE
## 2182        Suburban                66          344.2016         FALSE
## 2219        Suburban                65          468.0000         FALSE
## 1966          Rural                65          117.4504         FALSE
```

Note that these are primary variables identified in the EDA. We observed that the factor variables `is_unemployed` and `location_code` show a strong interaction with the `monthly_premium_auto` variable:

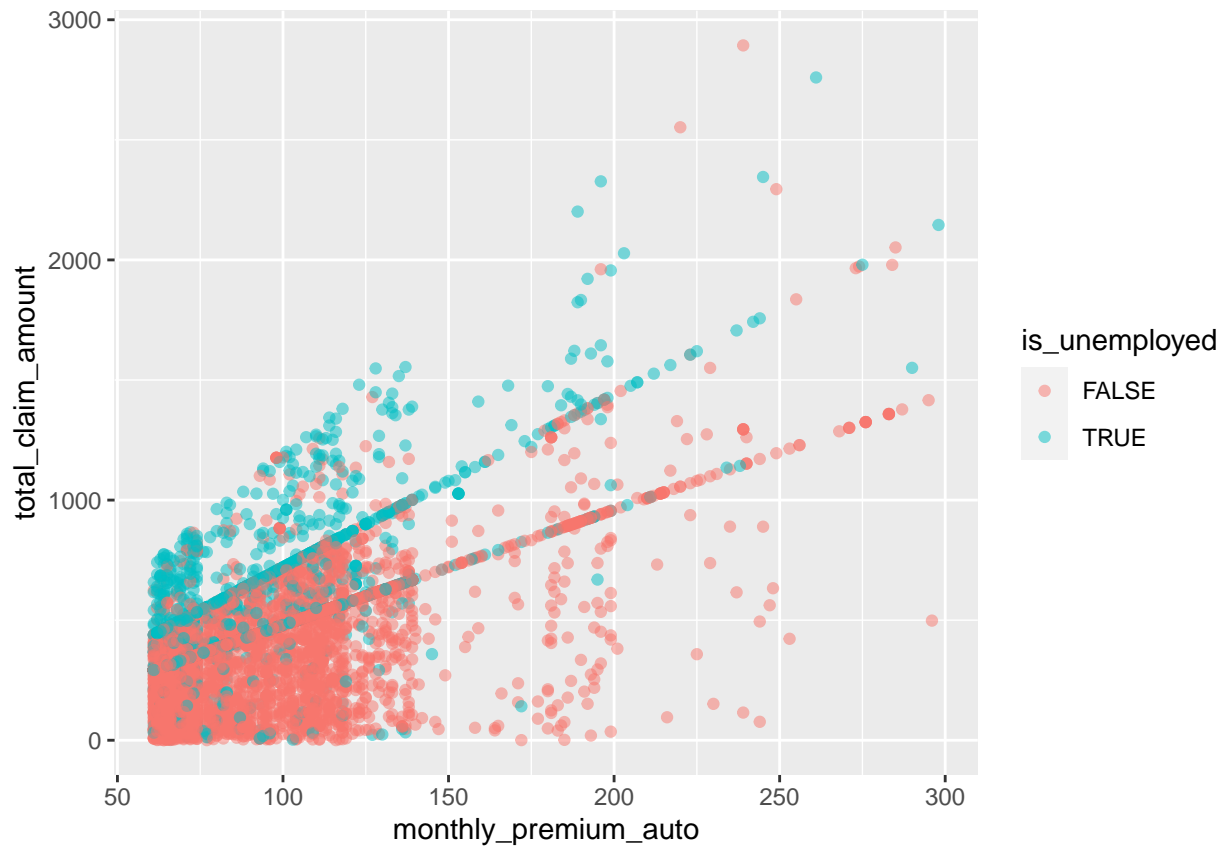

```
train_df %>%
  ggplot(aes(x = monthly_premium_auto, y = total_claim_amount,
             col = location_code)) +
  geom_point()
```

```
train_df_simple %>%
  ggplot(aes(x = monthly_premium_auto, y = total_claim_amount,
```

```
colour = is_unemployed)) +  
geom_point(alpha = 0.5)
```

The final, very simple model, using just three features is below. Including all the interaction terms seems to be important.

```
train_df_simple
```

##	location_code	monthly_premium_auto	total_claim_amount	is_unemployed

mae <- mean_abs_err(y_hat, test_df$total_claim_amount)
print(paste("MAE of:", round(mae, 2)))

## [1] "MAE of: 77.48"

```

Interpreting the model

We can visualise the effects:

```

effect <- t(t(mod$x) * mod$coefficients)

effect <- effect %>%
  as_tibble() %>%
  pivot_longer(everything(), names_to = "feature", values_to = "effect") %>%
  mutate(feature = str_replace(feature, "TRUE", ""))

```

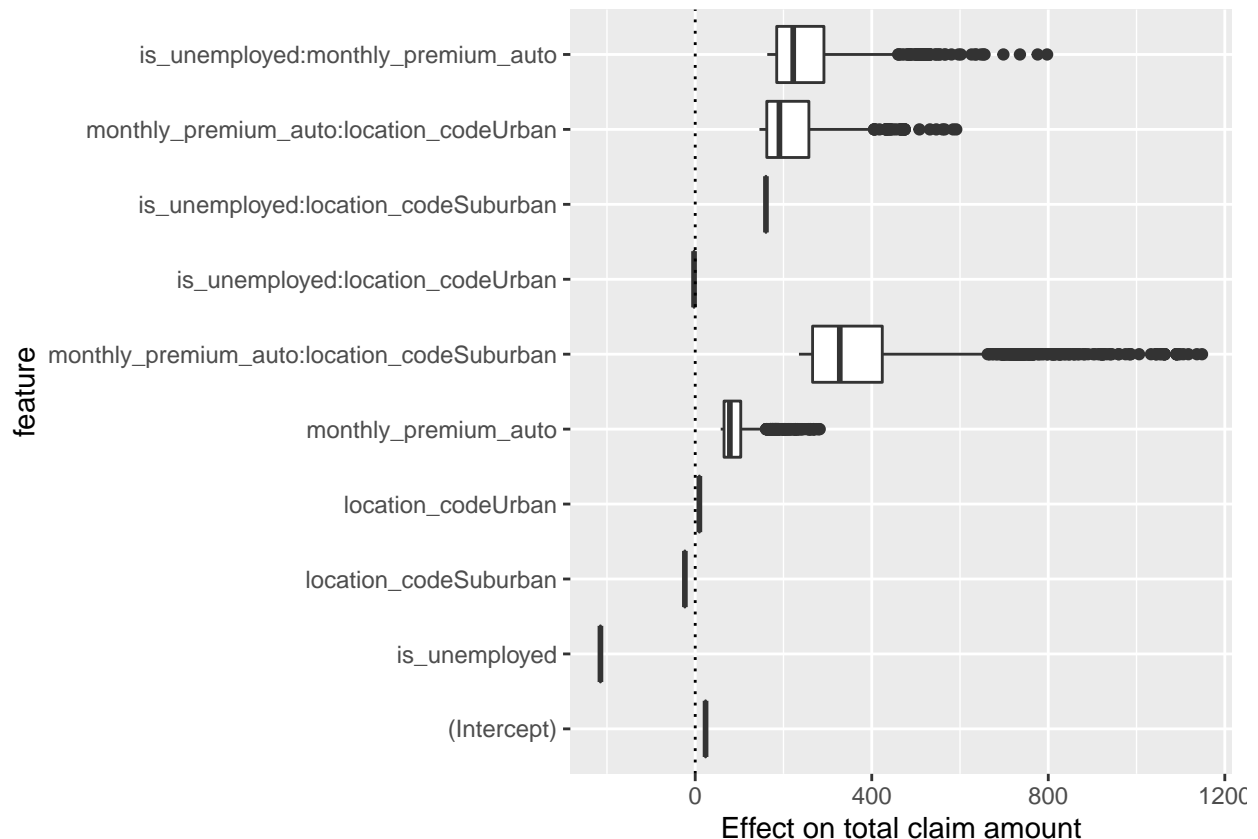

```

effect$feature <- factor(
  effect$feature,
  levels = unique(effect$feature)[rank(str_length(unique(effect$feature)))],
  ordered = TRUE
)

effect %>%
  filter(effect != 0) %>%
  ggplot(aes(x = effect, y = feature)) +
  geom_boxplot(aes(x = effect), orientation = "y", scale = "width") +
  geom_vline(data = NULL, xintercept = 0, linetype="dotted") +
  labs(x = "Effect on total claim amount")

```

Warning: Ignoring unknown parameters: scale

Now we have the best model. I will retrain it on the whole data set. Then this can be used to predict on the test set when it is released:

```

df <- rbind(train_df_simple, test_df_simple)

mod <- rq(total_claim_amount ~
  is_unemployed*monthly_premium_auto +
  location_code*monthly_premium_auto +
  is_unemployed*location_code, data = df)

```

Warning in rq.fit.br(x, y, tau = tau, ...): Solution may be nonunique

```
# Put test data here...
```
